Abstract

We summarize features and results on the problem of the existence of Ground States for the Nonlinear Schrödinger Equation on doubly-periodic metric graphs. We extend the results known for the two-dimensional square grid graph to the honeycomb, made of infinitely-many identical hexagons. Specifically, we show how the coexistence between one-dimensional and two-dimensional scales in the graph structure leads to the emergence of threshold phenomena known as dimensional crossover.

Keywords: periodic graphs, nonlinear Schrödinger, threshold phenomena, Sobolev inequality

AMS subject classification: 35Q55, 35R02

1. Introduction

In the last decade there has been a dramatic increase in the study of the dynamics of systems on metric graphs, or *networks*. This is mainly due to two different issues: first, the extensive use of mathematics in topics traditionally confined to a more qualitative approach (e.g. biology, social sciences, economics); second, the flexibility and the simplicity of networks as a mathematical environment to model phenomena occurring in the actual world.

Networks enter in the description of evolutionary phenomena on branched structures, namely, one-dimensional complexes made of *edges*, either finite or infinite, meeting at special points called *vertices*. Edges and vertices define the *topology* of the graph. The *metric* structure is defined by associating to every edge a *length* and then an arclength. This is easily accomplished by associating to every edge e a coordinate $x \in [0, \ell_e]$, where ℓ_e is the length of the edge.

Such a scheme applies to signals propagating in networks, circuits, and to more recent scientific and technological challenges of the new emerging field of research called *Atomtronics*.

The first appearance of metric graphs in the mathematical modeling of natural systems dates back to 1953 and is due to Ruedenberg and Scherr [1], who modeled a naphthalene array as a network of edges and vertices arranged in a hexagonal lattice, like a honeycomb. Then, a Hamiltonian operator representing the quantum energy of the system was defined on such a structure, and its spectrum was computed in order to deduce the possible values of the energy of the valence electrons. The paper is not only a milestone in physical chemistry, but it also introduces some important mathematical tools like the so-called *Kirchhoff's conditions* at the vertices of the graph, and it opens the research field of quantum graphs. Dealing with a standard quantum-mechanical system, the model is governed by a linear equation, i.e. the Schrödinger equation of the system.

Since then, the use of metric graphs has become widespread in the literature, exiting the realm of quantum mechanics and extending to electromagnetism, acoustics, and many others physically relevant contexts. However, most of the models were linear. The first systematic introduction to nonlinear dynamics on graphs was given by Ali Mehmeti [2] in a nowadays classical treatise published in 1994, but

[†]We acknowledge that the present research has been partially supported by MIUR grant Dipartimenti di Eccellenza 2018-2022 (E11G18000350001)

one had to wait about three decades to see the analysis of the dynamics of a specific nonlinear model, first given in [3] and concerning the effect of the impact of a fast soliton of the Nonlinear Schrödinger Equation (NLSE) on the vertex of an infinite star-graph. After this result, the research on the NLSE on graphs underwent an important development, especially because of great technical advances on the study of the mathematical aspects of the nonlinear Schrödinger Equation (especially following the seminal papers by Keel and Tao [4] and by Kenig and Merle [5]) from one side, and because of the rapid evolution of the technology of Bose-Einstein condensates (BEC) from the other, and in particular of the new accomplishments in the construction of *traps* of various shapes, to be used in BEC experiments.

In order to motivate the mathematical problem we are dealing with, let us be more specific on this point. A Bose-Einstein condensate is a system of a large (from thousands to millions) number of identical bosons, usually magnetically and/or optically confined in a spatial region, called *trap*. As predicted by Bose [6] and Einstein [7], under a prescribed value of the temperature, called "critical value", the system collapses into a very peculiar and non-classical state, in which:

- Every particle acquires an individual wave function (which is in general not the case for many-body systems, that are given a collective wave function only).
- The wave function is the same for all particles, and is called *wave function of the condensate*.
- The wave function of the condensate solves the following variational problem:

$$(1) \quad \min_{u \in H^1(\Omega), \int |u|^2 = N} E_{GP}(u)$$

where

- E_{GP} is the *Gross-Pitaevskii energy (GP) functional*, namely

$$(2) \quad E_{GP}(u) = \|\nabla u\|_{L^2(\Omega)}^2 + 8\pi\alpha \|u\|_{L^4(\Omega)}^4$$

(α is the scattering length of the two-body interaction between the particles in the condensate);

- Ω is the trap where the condensate is confined;
- N is the number of particles in the condensate;
- provided it exists, the minimum corresponds to a standing wave for the Gross-Pitaevskii *Nonlinear Schrödinger Equation*

$$i\partial_t \psi(t, x) = -\Delta \psi(t, x) + 32\pi\alpha |\psi(t, x)|^2 \psi(t, x).$$

Then it becomes an important issue to solve the problem of minimizing the functional (2) under the constraint $\int_{\Omega} |u|^2 dx = \mu$ given in (1). As one might expect, the result heavily depends on Ω , not only for what concerns the actual shape of the minimizer, but also for the sake of its mere existence. It is indeed this last issue that has been mostly studied during the last years, and will be the subject of the present note.

1.1. Existence of ground states: results

From now on, we consider a metric graph \mathcal{G} and the NLS energy functional defined as

$$(3) \quad E(u, \mathcal{G}) = \frac{1}{2} \int_{\mathcal{G}} |u'|^2 dx - \frac{1}{p} \int_{\mathcal{G}} |u|^p dx.$$

The first term is called *kinetic term*, as it represents the kinetic energy associated to the system, while the second is the *nonlinear term*.

The main difference of (3) with respect to the GP energy (2) is that in (3) a more general nonlinearity power is considered instead of the only case $p = 4$, but we restrict to the so-called focusing case, where the nonlinear term has a negative sign, and encodes the fact that the two-body interaction between the particles is attractive.

Owing to the choice of the sign, it is clear that there is a competition between the two terms: the kinetic term favours widespread signals, while the nonlinear term prevents the minimizers from dispersing too much. When a minimizer exists, it always realizes a compromise between the two terms and the two corresponding tendencies: spreading or squeezing.

We study the problem of minimizing the energy (3) with the constraint of constant mass, namely

$$(4) \quad \|u\|_{L^2(\mathcal{G})}^2 = \int_{\mathcal{G}} |u|^2 dx = \mu > 0.$$

We shall use the notation

$$(5) \quad \mathcal{E}(\mu) := \inf_{u \in H_{\mu}^1(\mathcal{G})} E(u, \mathcal{G}),$$

and introduce the ambient space

$$(6) \quad H_{\mu}^1(\mathcal{G}) := \{ u \in H^1(\mathcal{G}) : \|u\|_{L^2(\mathcal{G})}^2 = \mu \}$$

We call *ground state at mass μ* or, for short, *ground state*, every minimizer of (3) among all functions sharing the same mass μ .

First of all, it is well-known [8–10], that in the case of the real line, and provided that $2 < p < 6$, the compromise between kinetic and nonlinear term that gives rise to a ground state is realized for every μ by the *soliton*

$$(7) \quad \phi_{\mu}(x) = \mu^{\alpha} \phi_1(\mu^{\beta} x), \quad \alpha := \frac{2}{p-2}, \quad \beta := \frac{p-2}{6-p},$$

where the prototype soliton is denoted by ϕ_1 and equals

$$\phi_1(x) := C \operatorname{sech}(cx).$$

In the case of a real half-line \mathbb{R}^+ , by elementary symmetry arguments one can immediately realize that a solution exists for every value of the mass μ and it coincides with a half-soliton with the maximum at the origin, possibly multiplied by a phase factor.

Despite the result for the half-line and for the line (i.e. a pair of half-lines), for the graph made of three half-lines meeting one another at a single vertex (i.e. a *star graph*) it has been proven that there is no ground state, irrespectively of the choice of μ ([11]). Starting from this negative result, the problem of ensuring (or excluding) the existence of ground states for the NLS on graphs gained some popularity in the community, and some general results were found, isolating a key topological condition ([12]), studying in detail particular cases ([13–15]), dealing with compact graphs ([16,17]), introducing concentrated nonlinearities ([18–21]), focusing on the more challenging L^2 -critical case (i.e. $p = 6$ [22]). More recently, also some pioneering investigations of nonlinear Dirac equations has been initiated ([23,24]).

Figure 1. the two-dimensional square grid.

The analysis of NLS equations on periodic graphs has been developed for instance in ([25–27]), and a systematic discussion of the problem of ground states for periodic graphs has been carried out in [28], however here we shall focus on a particular phenomenon highlighted in [29] and called *dimensional crossover*. Investigating the problem of proving the existence or the nonexistence of ground states for the NLS on the regular two-dimensional square grid (see Figure 1), it was found that three different regimes come into play:

1. if $2 < p < 4$, then a ground state exists for every value μ of the mass;
2. if $p > 6$, then there is no ground state irrespectively of the value chosen for the mass;
3. if $p = 6$, then there is a particular value of the mass, called *critical mass* and denoted by μ^* , such that the infimum of the energy passes from 0 to $-\infty$ as the mass exceeds μ^* , and ground states never exist for any value of the mass;
4. if $4 \leq p < 6$, then there is a particular value of the mass, μ_p , such that ground states exist only beyond μ_p .

Now, points 1 and 2 are common to what one finds in the problem of the ground states in \mathbb{R} and \mathbb{R}^2 . The transition of the actual value of the infimum of the energy as in point 3 is characteristic of one-dimensional domains, in particular of quantum graphs made of a compact core and a certain number of half-lines.

What really distinguishes the case of the grid graph from the previously studied cases of quantum graphs is point 4, where an unprecedented behaviour is detected for nonlinearity powers ranging from 4 to 6. Here power 4 is meaningful since it is the critical power for two-dimensional problems. Then, the fact that power 4 corresponds to a transition in the behaviour of the problem reveals that the two-dimensional structure is emerging.

Qualitatively, the grid is two-dimensional on a large scale, and this fact must emerge when searching for low-mass ground states, since low-mass means widespread functions.

From a quantitative point of view, the emergence of the two-dimensional large scale structure occurs in the validity of the *two-dimensional Sobolev inequality*, i.e.

$$(8) \quad \|u\|_{L^2(\mathcal{G})} \leq C \|u'\|_{L^1(\mathcal{G})} \quad (u \in W^{1,1}(\mathcal{G})).$$

As well-known in Functional Analysis, such an inequality is typical of two-dimensional domains, whereas in one-dimension one has the *one-dimensional Sobolev inequality*

$$(9) \quad \|u\|_{L^\infty(\mathcal{G})} \leq C \|u'\|_{L^1(\mathcal{G})} \quad (u \in W^{1,1}(\mathcal{G})).$$

Now, inequality (9) is easy to prove for every one-dimensional non-compact graph, just using

$$u(x) = \int_{\gamma} u'(t) dt$$

where x is any point of the graph and the symbol γ denotes a path isomorphic to a half-line starting at x . The existence of such a path is ensured by the fact that the graph is non-compact (therefore it extends up to infinity) and connected (so that it is possible to reach the infinity from x through a sequence of adjacent edges).

It is then clear that what marks the transition between the one and the two-dimensional regime is the coexistence of (9) and (8), so that what really characterizes the grid, as well as every structure displaying a two-dimensional nature in the large scale, is the validity of (8).

As one shall expect, such a portrait can be generalized to the setting of periodic graphs exploiting higher dimensional structures in the large scale, like regular n -dimensional grids. In this context, it is readily seen that the dimensional crossover takes place between the one-dimensional and the n -dimensional critical power (see [30] for the explicit discussion of the case $n = 3$).

In this paper we show that for the *honeycomb graph*, namely the grid made of the periodic repetition of a hexagon along a two-dimensional mesh (see Figure 2), estimate (8) holds true. Moving from this fact, we deduce a complete result about the existence or nonexistence of ground states, closely following the steps introduced in [29].

 Figure 2. The infinite two-dimensional hexagonal grid \mathcal{G} .

1.2. Existence of ground states in the honeycomb: the complete result

Let us summarize the roadmap followed in [29], since for the sake of studying the hexagonal grid the steps will be the same. We shall therefore develop in detail only the part that differs significantly from the case of the square grid.

As explained in Section 1.1, our task is to prove the validity of a Sobolev inequality. This will be accomplished in Theorem 3.1. Once found the correct Sobolev inequality, and starting from it, we will prove another family of estimates, called Gagliardo-Nirenberg inequalities, that estimate the potential term in (3) by the product of suitable powers of the mass and of the kinetic energy.

In the case of functions on the line, as well as on general metric graphs, such estimates read as follows

$$(10) \quad \|u\|_{L^p(\mathcal{G})}^p \leq C \|u'\|_{L^2(\mathcal{G})}^{\frac{p}{2}-1} \|u\|_{L^2(\mathcal{G})}^{\frac{p}{2}+1},$$

and, inserted in (3), give

$$(11) \quad E(u, \mathcal{G}) \geq \frac{1}{2} \|u'\|_{L^2(\mathcal{G})}^2 - \frac{C}{p} \|u'\|_{L^2(\mathcal{G})}^{\frac{p}{2}-1} \mu^{\frac{p}{4}+\frac{1}{2}}$$

from which one immediately concludes that, if $2 < p < 6$, then

$$\mathcal{E}(\mu) > -\infty,$$

that is a necessary condition for the existence of a ground state. In order to conclude for the existence, one should then prove the convergence of minimizing sequences. Let us just give some hint on how this proof may work. For details we refer the reader to [29]. First, to avoid that the minimizing sequence runs away, converging then to zero in the weak sense, one should localize the functions of the sequence. This is easily accomplished by exploiting the periodicity of the graph, by which, given a minimizing sequence, one defines a new minimizing sequence translating the elements of the old one in such a way that every function has its maximum on a fixed edge. Once excluded the possibility of escaping at infinity, the only way for a minimizing sequence in order not to converge is to spread along the grid, reaching in the limit zero energy.

As a consequence, in order to show that a minimizing sequence converges, it suffices to exhibit a function with negative energy.

The existence of a function with negative energy in the cases $2 < p < 4$ for every μ , and $4 \leq p < 6$ for μ large enough, is the content of Theorem 1.1 and of the positive part of point (i) in Theorem 1.2.

Conversely, in order to catch the core of the non-existence results at points (ii) and (iii) in Theorem 1.2, let us consider inequality (10) and notice that for $p = 6$ it specializes to

$$(12) \quad \|u\|_{L^6(\mathcal{G})}^6 \leq C \|u'\|_{L^2(\mathcal{G})}^2 \|u\|_{L^2(\mathcal{G})}^4.$$

On the other hand, from (8) one derives

$$(13) \quad \|u\|_{L^p(\mathcal{G})}^p \leq C \|u'\|_{L^2(\mathcal{G})}^{p-2} \|u\|_{L^2(\mathcal{G})}^2,$$

that, for $p = 4$, gives

$$(14) \quad \|u\|_{L^4(\mathcal{G})}^4 \leq C \|u'\|_{L^2(\mathcal{G})}^2 \|u\|_{L^2(\mathcal{G})}^2.$$

Now, interpolating between (12) and (14) one has, for every $p \in [4, 6]$

$$(15) \quad \|u\|_{L^p(\mathcal{G})}^p \leq C \|u'\|_{L^2(\mathcal{G})}^2 \|u\|_{L^2(\mathcal{G})}^{p-2}.$$

Then, by (15)

$$(16) \quad \begin{aligned} E(u, \mathcal{G}) &\geq \frac{1}{2} \|u'\|_{L^2(\mathcal{G})}^2 - \frac{C}{p} \|u'\|_{L^2(\mathcal{G})}^2 \|u\|_{L^2(\mathcal{G})}^{p-2} \\ &= \frac{1}{2} \|u'\|_{L^2(\mathcal{G})}^2 \left(1 - \frac{2C}{p} \mu^{\frac{p}{2}-1} \right) \end{aligned}$$

Then, for every $p \in [4, 6]$ there exists a positive value $\mu_p > 0$ given by

$$\mu_p := \left(\frac{p}{2C} \right)^{\frac{2}{p-2}},$$

with C being the sharpest constant in (15), such that

- If $\mu < \mu_p$, then $E(u, \mathcal{G}) > 0$ for every $u \in H_\mu^1(\mathcal{G})$. Since, by spreading the function u along the grid, one immediately gets $\mathcal{E}(\mu) = 0$, it turns out that the infimum is not attained and ground states do not exist.
- If $\mu > \mu_p$ it turns out that $\mathcal{E}(\mu) < 0$, and possibly $-\infty$.

The dimensional crossover lies exactly in this continuous transition from the subcritical regime (where for every mass there is a ground state) to the supercritical, where there are values of the mass in correspondence of which the energy is not lower bounded. In standard cases, such a transition only occurs in correspondence of the unique critical case, that amounts to 6 in dimension one, and to 4 in dimension two. In the case of a doubly periodic graph as the honeycomb we consider here, this actually takes place for all the nonlinearities p between 4 and 6, so that a continuum of critical exponents arises between the critical power of dimension 2 and the one of dimension 1.

Here are the complete results:

Theorem 1.1. *Let $2 < p < 4$. Then, for every $\mu > 0$, there exists a ground state of mass μ .*

Theorem 1.2. *For every $p \in [4, 6]$ there exists a critical mass $\mu_p > 0$ such that*

(i) *if $p \in (4, 6)$ then ground states of mass μ exist if and only if $\mu \geq \mu_p$, and*

$$(17) \quad \mathcal{E}(\mathcal{G}) \begin{cases} = 0 & \text{if } \mu \leq \mu_p \\ < 0 & \text{if } \mu > \mu_p. \end{cases}$$

(ii) *if $p = 4$ then ground states of mass μ exist if $\mu > \mu_4$ and they do not exist if $\mu \leq \mu_4$. Furthermore, (17) holds true also in the case $p = 4$.*

(iii) if $p = 6$ then ground states never exist, independently of the value of μ , and

$$(18) \quad \mathcal{E}(\mu) = \begin{cases} 0 & \text{if } \mu \leq \mu_6 \\ -\infty & \text{if } \mu > \mu_6. \end{cases}$$

Theorems 1.1 and 1.2 do not differ from their analogues in the case of the square grid, treated in [29]. The only remarkable new procedures concern the proof of Sobolev inequality as in Theorem 3.1 and the construction of a function with negative energy proving the existence of a ground state in the regime $p \in (2, 4)$.

The remainder of the paper is organised as follows. Section 2 sets some notation for the honeycomb, whereas Section 3 develops the proof of Sobolev inequality (9). Finally, in Section 4 we exhibit functions realizing strictly negative energy when $p \in (2, 4)$, giving the proof of Theorem 1.1.

2. Notation

Before going further, a bit of notation is necessary. Particularly, to ease several of the upcoming arguments, it is useful to decompose the hexagonal grid in two family of parallel infinite paths, so that the whole graph \mathcal{G} can be described as their union.

To this purpose, let us introduce the following construction. Fix any cell in \mathcal{G} and denote by o its lower left vertex. Note that, starting at o , there is one horizontal edge at the right and, at the left of o , an edge directed upwards and another one directed downwards. Consider then the infinite path running through o constructed in this way. First, moving from o to the right, follow the infinite path that alternates a horizontal and an upward edge. Then, moving from o to the left, follow the infinite path that alternates a downward and a horizontal edge. We denote by L_0 the union of these two paths (see Figure 3(a)).

Similarly, consider both the infinite path that goes from o to the left alternating an upward and a horizontal edge, and the one that originates at o and moves to the right alternating a horizontal and a downward edge. We denote the union of these two by R_0 (see Figure 3(b)).

Figure 3. the paths L_0 (a) and R_0 (b).

Note that both on L_0 and on R_0 natural coordinates $x_{L_0} : L_0 \rightarrow (-\infty, +\infty)$, $x_{R_0} : R_0 \rightarrow (-\infty, +\infty)$ can be defined, so that they can be identified with real lines with the origin in o .

Now, consider for instance the vertex belonging to L_0 which is at distance 2ℓ (measured along \mathcal{G}) from o on its right. It is immediate to see that an infinite path running through this vertex and parallel to R_0 can be recovered by repeating the procedure used to construct R_0 . However, this is not the case if we consider the vertex of L_0 at distance ℓ from o on its right, as it already belongs to R_0 .

More generally, through every vertex on L_0 located at an even distance from o on its right runs an infinite path parallel to R_0 . It is then straightforward to check that the same holds true also for every vertex on L_0 located at an odd (in terms of ℓ) distance from o at its left (whereas vertices at even distances

on the left do not provide any additional path). This leads to a family $\{R_j\}_{j \in \mathbb{Z}}$ of infinite parallel paths in \mathcal{G} .

Analogously, one can consider the family of infinite paths $\{L_i\}_{i \in \mathbb{Z}}$ all parallel to L_0 , constructed by taking any vertex on R_0 either at an even distance from o at its right or at odd distance from o at its left and repeating the steps in the construction of L_0 .

We stress the fact that the set defined by $\left(\bigcup_{i \in \mathbb{Z}} L_i\right) \cap \left(\bigcup_{j \in \mathbb{Z}} R_j\right)$ is composed by all the horizontal edges of \mathcal{G} and for this reason it follows

$$\mathcal{G} \subset \left(\bigcup_{i \in \mathbb{Z}} L_i\right) \cup \left(\bigcup_{j \in \mathbb{Z}} R_j\right).$$

In particular $L_i \cap R_j \neq \emptyset$ for every $i, j \in \mathbb{Z}$, as they share exactly one horizontal edge.

Finally, given $i, j \in \mathbb{Z}$, we denote by $I_i^j \subset L_i$ the union of the horizontal edge that L_i shares with R_j and the upward edge on its right. Moreover, we call v_i^j the first vertex of I_i^j that we meet walking down R_j from $-\infty$ (see Figure 4(a)). Note that, for every i , $L_i = \bigcup_{j \in \mathbb{Z}} I_i^j$. Similarly, we define J_j^i as the union of the horizontal edge shared by L_i and R_j and the upward edge at its left. As before, we observe that, for every $j \in \mathbb{Z}$, $R_j = \bigcup_{i \in \mathbb{Z}} J_j^i$ and again we denote by w_j^i the first vertex of J_j^i that we encounter walking through L_i from $-\infty$ (Figure 4(b)).

Figure 4. The subsets I_i^j (a) and J_j^i (b).

3. Sobolev inequality

This section is devoted to the derivation of some functional inequalities that describe in which sense the hexagonal grid graph \mathcal{G} interpolates between one-dimensional and two-dimensional behaviour. Particularly, the two-dimensional nature of the graph shows up explicitly with the following result, stating the validity of the Sobolev inequality in the form typical of dimension two.

Theorem 3.1. *For every $u \in W^{1,1}(\mathcal{G})$,*

$$(19) \quad \|u\|_{L^2(\mathcal{G})} \leq 2\sqrt{2l}\|u'\|_{L^1(\mathcal{G})}.$$

Proof. We beforehand remind that $\mathcal{G} \subset \left(\bigcup_{i \in \mathbb{Z}} L_i\right) \cup \left(\bigcup_{j \in \mathbb{Z}} R_j\right)$, so that

$$(20) \quad \|u\|_{L^2(\mathcal{G})}^2 \leq \sum_i \|u\|_{L^2(L_i)}^2 + \sum_j \|u\|_{L^2(R_j)}^2.$$

In order to prove (19), we aim at estimating the two terms on the right side of (20). Let us start with $\sum_i \|u\|_{L^2(L_i)}^2$, where $\|u\|_{L^2(L_i)}^2 = \int_{L_i} |u(x)|^2 dx$.

Consider any point $x \in \mathcal{G}$ located on L_i . Observe that x can be reached following at least two different paths on \mathcal{G} . The first one walks through L_i from $-\infty$ to x , whereas the second one runs through R_j from $-\infty$ to the vertex v_i^j and then moves on L_i from v_i^j to x (Figure 5). Identifying with some abuse of notation the points x and v_i^j with their corresponding coordinates $x_{L_i}(x)$, $x_{L_i}(v_i^j)$ and $x_{R_j}(v_i^j)$, we denote by $L_i(-\infty, x)$, $R_j(-\infty, v_i^j)$ and $L_i(v_i^j, x)$ the paths from $-\infty$ to x along L_i , from $-\infty$ to v_i^j along R_j and from v_i^j to x along L_i , respectively.

Thus, we get

$$(21) \quad u(x) = \int_{L_i(-\infty, x)} u'(\tau) d\tau$$

and

$$(22) \quad u(x) = \int_{R_j(-\infty, v_i^j)} u'(\tau) d\tau + \int_{L_i(v_i^j, x)} u'(\tau) d\tau.$$

Multiplying (21) and (22) and using the fact that $L_i(-\infty, x) \subset L_i$, $R_j(-\infty, v_i^j) \subset R_j$ and $L_i(v_i^j, x) \subset I_i^j$, we estimate

$$\begin{aligned} |u(x)|^2 &= \left| \int_{L_i(-\infty, x)} u'(\tau) d\tau \right| \cdot \left| \int_{R_j(-\infty, v_i^j)} u'(\tau) d\tau + \int_{L_i(v_i^j, x)} u'(\tau) d\tau \right| \\ &\leq \left(\int_{L_i(-\infty, x)} |u'(\tau)| d\tau \right) \cdot \left(\int_{R_j(-\infty, v_i^j)} |u'(\tau)| d\tau + \int_{L_i(v_i^j, x)} |u'(\tau)| d\tau \right) \\ &\leq \left(\int_{L_i} |u'(\tau)| d\tau \right) \cdot \left(\int_{R_j} |u'(\tau)| d\tau + \int_{I_i^j} |u'(\tau)| d\tau \right). \end{aligned}$$

Then, integrating on L_i

$$(23) \quad \int_{L_i} |u(x)|^2 dx = \int_{L_i} |u'(\tau)| d\tau \left(\int_{L_i} \left(\int_{R_j} |u'(\tau)| d\tau + \int_{I_i^j} |u'(\tau)| d\tau \right) dx \right).$$

Recall that $L_i = \bigcup_{j \in \mathbb{Z}} I_i^j$ and note that both $\int_{R_j} |u'(\tau)| d\tau$ and $\int_{I_i^j} |u'(\tau)| d\tau$ are piecewise constant on each I_i^j as functions of x . Hence, there results

$$(24) \quad \int_{L_i} \left(\int_{R_j} |u'(\tau)| d\tau \right) dx = 2l \sum_{j \in \mathbb{Z}} \int_{R_j} |u'(\tau)| d\tau,$$

and

$$(25) \quad \int_{L_i} \left(\int_{I_i^j} |u'(\tau)| d\tau \right) dx = 2l \sum_{j \in \mathbb{Z}} \int_{I_i^j} |u'(\tau)| d\tau = 2l \int_{L_i} |u'(\tau)| d\tau.$$

By (23), (24) and (25) it follows

$$\begin{aligned} \int_{L_i} |u(x)|^2 dx &= \int_{L_i} |u'(\tau)| d\tau \left(2l \sum_{j \in \mathbb{Z}} \int_{R_j} |u'(\tau)| d\tau + 2l \int_{L_i} |u'(\tau)| d\tau \right) \\ &\leq 4l \|u'\|_{L^1(\mathcal{G})} \int_{L_i} |u'(\tau)| d\tau, \end{aligned}$$

as each term in the sum can be dominated by $\|u'\|_{L^1(\mathcal{G})}$.

Finally, summing over $i \in \mathbb{Z}$ yields

$$\sum_{i \in \mathbb{Z}} \int_{L_i} |u(x)|^2 \leq 4l \|u'\|_{L^1(\mathcal{G})} \sum_{i \in \mathbb{Z}} \int_{L_i} |u'(\tau)| d\tau \leq 4l \|u'\|_{L^1(\mathcal{G})}^2.$$

Figure 5. The paths from $-\infty$ to x along L_i (a) and R_j (b) as in the proof of Theorem 3.1.

The same procedure can be adapted to estimate $\sum_{j \in \mathbb{Z}} \int_{R_j} |u(x)|^2 dx$, replacing I_i^j with J_j^i whenever needed, so that by (20) we end up with

$$\|u\|_{L^2(\mathcal{G})}^2 \leq 8\ell \|u'\|_{L^1(\mathcal{G})}^2. \quad \square$$

Arguing as in the proof of Theorem 2.3 in [29], it can then be proved that Theorem 3.1 entails the following two-dimensional Gagliardo-Nirenberg inequality on \mathcal{G}

$$(26) \quad \|u\|_{L^p(\mathcal{G})}^p \leq C \|u\|_{L^2(\mathcal{G})}^2 \|u'\|_{L^2(\mathcal{G})}^{p-2}$$

for every $u \in H^1(\mathcal{G})$ and $p \geq 2$ (here C denotes a universal constant).

On the other hand, as for every non-compact metric graph, it is known that also the one-dimensional Gagliardo-Nirenberg inequality

$$(27) \quad \|u\|_{L^p(\mathcal{G})}^p \leq \|u\|_{L^2(\mathcal{G})}^{\frac{p}{2}+1} \|u'\|_{L^2(\mathcal{G})}^{\frac{p}{2}-1}$$

holds true on \mathcal{G} , again for every $u \in H^1(\mathcal{G})$ and $p \geq 2$ (for a simple proof relying on the theory of rearrangements on graphs see for instance [31]).

Hence, combining (26)–(27), a new version of the Gagliardo-Nirenberg inequality can be derived, which we refer to as *interpolated Gagliardo-Nirenberg inequality*, that accounts for the dimensional crossover in Theorem 1.2. Indeed, for every $p \in [4, 6]$ there exists a constant K_p , depending only on p , such that

$$\|u\|_{L^p(\mathcal{G})}^p \leq K_p \|u\|_{L^2(\mathcal{G})}^{p-2} \|u'\|_{L^2(\mathcal{G})}^2$$

for every $u \in H^1(\mathcal{G})$ (as the argument is the same, we refer to Corollary 2.4 in [29] for a complete proof of this fact).

4. Existence result: proof of Theorem 1.1

In this section, we provide the proof of Theorem 1.1, showing that if p is smaller than 4, then ground states always exist for every value of the mass.

To this purpose, we first recall a general compactness result, originally proved in Proposition 3.3 of [29], which is valid for every doubly periodic metric graphs, so that it also applies in the case of the two-dimensional hexagonal grid we are dealing with.

Proposition 4.1 (Proposition 3.3, [29]). *Let $p < 6$ and $\mu < 0$. If $\mathcal{E}(\mu) < 0$, then a ground state with mass μ exists.*

Proof of Theorem 1.1. In view of Proposition 4.1, given $\mu > 0$, it is enough to prove that $\mathcal{E}(\mu) < 0$ to show that ground states in $H_\mu^1(\mathcal{G})$ exist.

We consider the following construction. For every $i \in \mathbb{Z}$, recall that L_i is identified with a real line $(-\infty, +\infty)$ through a coordinate x_{L_i} , and we are free to choose which vertex $v \in L_i$ corresponds to the origin $x_{L_i}(v) = 0$. We thus fix the origin of each L_i in the following way. First, set the origin of L_0 at any of its vertices being the left endpoint of a horizontal edge. Then, since the upward edge on the left of this vertex connects L_0 with L_1 , set the origin of L_1 at the endpoint of this bridging edge. Let then \bar{L}_0 be the straight line in the plane passing through both the origin of L_0 and the one of L_1 . For each $i \in \mathbb{Z}$, \bar{L}_0 intersects L_i in exactly one vertex of \mathcal{G} , so that we set this point to be the origin of L_i .

Note that the intersection of \bar{L}_0 with the whole grid \mathcal{G} is a disjoint union of edges, each joining a couple of paths L_i, L_{i+1} , for some $i \in \mathbb{Z}$. Precisely, we write

$$\bar{L}_0 \cap \mathcal{G} = \bigsqcup_{i \in \mathbb{Z}} b_{2i}^0$$

where, given $i \in \mathbb{Z}$, b_{2i}^0 denotes the bridging edge between L_{2i} and L_{2i+1} that belongs to \bar{L}_0 .

Similarly, for every $k \in \mathbb{Z}$, let \bar{L}_k be the straight line in the plane parallel to \bar{L}_0 passing through the vertex of $v \in L_0$ corresponding to $x_{L_0}(v) = k$, so that

$$\bar{L}_k \cap \mathcal{G} = \begin{cases} \bigsqcup_{i \in \mathbb{Z}} b_{2i}^k & \text{if } k \text{ even} \\ \bigsqcup_{i \in \mathbb{Z}} b_{2i-1}^k & \text{if } k \text{ odd} \end{cases}$$

where again b_{2i}^k (resp. b_{2i-1}^k) is the edge of \mathcal{G} joining L_{2i} with L_{2i+1} (resp. L_{2i-1} with L_{2i}) that belongs to \bar{L}_k .

Moreover, identifying each b_j^k with the interval $[0, 1]$ through the coordinate $x_{b_j^k} : b_j^k \rightarrow [0, 1]$, we use the following notation: if $j \geq 0$, then we set $x_{b_j^k}(v) = 0$ for $v = b_j^k \cap L_j$, whereas if $j < 0$, then we set $x_{b_j^k}(0) = v$ for $v = b_j^k \cap L_{j+1}$.

Then, given $\varepsilon > 0$, we define (see Figure 6)

$$u_\varepsilon(x) := \begin{cases} e^{-\varepsilon(|x|+|i|)} & \text{if } x \in L_i, \text{ for some } i \in \mathbb{Z} \\ e^{-\varepsilon(|x|+|i|+j)} & \text{if } x \in b_j^i, \text{ for some } j, k \in \mathbb{Z}, j \geq 0 \\ e^{-\varepsilon(|x|+|i|+|j+1|)} & \text{if } x \in b_j^i, \text{ for some } j, k \in \mathbb{Z}, j < 0. \end{cases}$$

By construction, $u \in H^1(\mathcal{G})$ and, given $i \in \mathbb{Z}$,

$$\begin{aligned} \int_{L_i} |u_\varepsilon|^p dx &= 2 \int_0^{+\infty} e^{-p\varepsilon(x+|i|)} dx = \frac{2e^{-p\varepsilon|i|}}{p\varepsilon} \\ \int_{\bar{L}_i \cap \mathcal{G}} |u_\varepsilon|^p dx &= \int_0^{+\infty} e^{-p\varepsilon(x+|i|)} dx = \frac{e^{-p\varepsilon|i|}}{p\varepsilon} \end{aligned}$$

for every $p \geq 2$ and

$$\begin{aligned} \int_{L_i} |u'_\varepsilon|^2 dx &= 2\varepsilon^2 \int_0^{+\infty} e^{-2\varepsilon(x+|i|)} dx = \varepsilon e^{-2\varepsilon|i|} \\ \int_{\bar{L}_i \cap \mathcal{G}} |u'_\varepsilon|^2 dx &= \varepsilon^2 \int_0^{+\infty} e^{-2\varepsilon(x+|i|)} dx = \frac{\varepsilon e^{-2\varepsilon|i|}}{2}. \end{aligned}$$

Since $\mathcal{G} = \left(\bigcup_{i \in \mathbb{Z}} L_i \right) \cup \left(\bigcup_{i \in \mathbb{Z}} \bar{L}_i \cap \mathcal{G} \right)$, we get

Figure 6. the construction of the function u in the proof of Theorem 1.1, with the straight lines \overline{L}_i and the values of u at the vertices of \mathcal{G} .

$$\begin{aligned} \int_{\mathcal{G}} |u_\varepsilon|^p dx &= \sum_{i \in \mathbb{Z}} \int_{L_i} |u_\varepsilon|^p dx + \sum_{i \in \mathbb{Z}} \int_{\overline{L}_i \cap \mathcal{G}} |u_\varepsilon|^p dx = 3 \left(\frac{1}{p\varepsilon} + 2 \sum_{i=1}^{\infty} \frac{e^{-p\varepsilon i}}{p\varepsilon} \right) = \frac{3(e^{p\varepsilon} + 1)}{p\varepsilon(e^{p\varepsilon} - 1)} \\ \int_{\mathcal{G}} |u'_\varepsilon|^2 dx &= \sum_{i \in \mathbb{Z}} \int_{L_i} |u'_\varepsilon|^2 dx + \sum_{i \in \mathbb{Z}} \int_{\overline{L}_i \cap \mathcal{G}} |u'_\varepsilon|^2 dx = 3 \left(\frac{\varepsilon}{2} + \sum_{i=1}^{\infty} \varepsilon e^{-2\varepsilon i} \right) = \frac{3\varepsilon(e^{2\varepsilon} + 1)}{2(e^{2\varepsilon} - 1)}. \end{aligned}$$

Hence, setting

$$k_\varepsilon := \left(\frac{2\varepsilon(e^{2\varepsilon} - 1)}{3(e^{2\varepsilon} + 1)} \mu \right)^{1/2}$$

and letting

$$v_\varepsilon(x) := k_\varepsilon u_\varepsilon(x) \quad \forall x \in \mathcal{G}$$

yields

$$\|v_\varepsilon\|_{L^2(\mathcal{G})}^2 = k_\varepsilon^2 \int_G |u_\varepsilon|^2 dx = \mu.$$

Therefore, $v_\varepsilon \in H_\mu^1(\mathcal{G})$ for every $\varepsilon > 0$ and, taking advantage of the explicit formula above, as $\varepsilon \rightarrow 0$

$$E(v_\varepsilon, \mathcal{G}) = \frac{1}{2} k_\varepsilon^2 \int_{\mathcal{G}} |u'_\varepsilon|^2 dx - \frac{1}{p} k_\varepsilon^p \int_{\mathcal{G}} |u_\varepsilon|^p dx \sim \frac{1}{2} \mu \varepsilon^2 - \frac{1}{p} C \mu^{p/2} \varepsilon^{p-2}$$

for some $C > 0$ depending only on p . Thus, whenever $p < 4$ and ε is small enough, we have

$$\mathcal{E}(\mu) \leq E(v_\varepsilon, \mathcal{G}) < 0$$

and we conclude.
