An updated distribution of *Solidago ×niederederi* (Asteraceae) in Poland. – Acta Mus. Siles. Sci. Natur., 66: 253-258, 2017.

Abstract: In this paper, an updated map of the distribution of *Solidago ×niederederi*, a natural hybrid between *S. canadensis* and *S. virgaurea*, in Poland is presented using the ATPOL cartogram method. A compiled list of 55 localities of the hybrid within 40 cartogram units (10-km squares) is provided and its negative impact on *S. virgaurea* is highlighted.

Key words: alien species, biological recording, Central Europe, geographical range, hybrid.

Introduction

Solidago ×niederederi Khek (Asteraceae), a natural hybrid between North American *S. canadensis* L. s. l. and European *S. virgaurea* L. s. str., was described from Austria at the beginning of the 20th century (Khek 1905, Pliszko 2015a, Pliszko & Zalewska-Gałosz 2016). Nowadays, it is known from a dozen countries in Europe, including Austria, Italy, the United Kingdom, Denmark, Sweden, Norway, Germany, Poland, Lithuania, Latvia, and Russia (Nilsson 1976, Burton 1980, Sunding 1989, Mayorov *et al.* 2012, Pliszko 2013, Stace *et al.* 2015, Gudžinskas & Petrušaitis 2016, Karpavičienė & Radušienė 2016, Pagitz 2016, Pliszko & Zalewska-Gałosz 2016). As a hybrid between alien and native species, it should be treated as alien taxon in Europe, according to Pyšek *et al.* (2004). *Solidago ×niederederi* is a perennial plant morphologically more or less intermediate between its parental species (Nilsson 1976, Pliszko 2013, Gudžinskas & Žalneravičius 2016, Karpavičienė & Radušienė 2016). It forms characteristic clonal clusters of shoots (generative and vegetative ramets) similar to those found in *S. canadensis* and *S. virgaurea*. However, there is no evidence that the hybrid (at least the F₁ generation) produces long rhizomes typical of *S. canadensis* (Pliszko & Kostrakiewicz-Gierałt 2017). Nevertheless, the hybrid is able to produce numerous generative ramets and viable seedlings (F₂ generation) as a part of its naturalization strategy (Pliszko & Kostrakiewicz-Gierałt 2017). In this respect, it should be pointed out that *S. ×niederederi* spreads by wind-dispersed achenes, however, the seed-set in the hybrid is limited by its reduced pollen viability (Migdałek *et al.* 2014, Karpavičienė & Radušienė 2016). *Solidago ×niederederi* usually occurs in disturbed areas where *S. canadensis* and *S. virgaurea* share the habitats. It is found on abandoned fields, roadside verges and slopes, railway embankments, in disused quarries and tree plantations, often close to both parental species (Nilsson 1976, Pliszko 2013, Stace *et al.* 2015, Gudžinskas & Petrušaitis 2016, Pliszko & Zajac 2016, Pliszko & Kostrakiewicz-Gierałt 2017).

The first record of *S. ×niederederi* in Poland was provided by Rostański (1971) who identified it among the herbarium materials (one specimen) collected by Ambrożewska in Drohiczyn, Podlaskie Province, in 1957. This specimen is deposited at the Herbarium of the Faculty of Biology of the University of Warsaw (WA0000035527!). Up to 2016, more than 40 localities of the hybrid have been registered in the north-eastern, central, western, and southern parts of the country (Pliszko 2013, 2015b, Pliszko & Zajac 2016, Jaźwa *et al.* 2018, Pliszko & Kostrakiewicz-Gierałt 2017). However, not all of them were presented in reference to the ATPOL cartogram grid (Zajac 1978). The aim of this study is to update the distribution of *S. ×niederederi* in Poland, with new unpublished records, using the ATPOL cartogram method.

Material and methods

New records of *Solidago × niederedederi* were obtained during field surveys conducted in 2014–2017. Published data on the occurrence of the hybrid in Poland were also included (Rostański 1971, Pliszko 2013, 2015b, Pliszko & Zajęc 2016, and Jaźwa *et al.* 2018). Identification of *S. × niederedederi* followed morphological features given by Nilsson (1976) and Gudžinskas & Žalneravičius (2016). Distribution map was prepared based on the ATPOL cartogram method (Zajęc 1978), involving 10-km square as a basic cartogram unit. Localities were revised using the Online ATPOL grid (Komsta 2016, www.komsta.net/atpol). Voucher specimens of *S. × niederedederi* are deposited in the Herbarium of the Institute of Botany of the Jagiellonian University in Kraków (KRA), the Herbarium of the Department of Biology and Environment Protection of the Nicolaus Copernicus University in Toruń (TRN), and the Herbarium of the Białowieża Geobotanical Station of the University of Warsaw (BSG), as well as in one private herbarium collection.

Results

In this study, distribution of *Solidago × niederedederi* in Poland is updated with 10 new localities which are situated within seven new cartogram units (10-km squares) and three known cartogram units (10-km squares) of the ATPOL grid. Currently, the hybrid is known from 55 localities situated within 40 cartogram units (10-km squares) of the ATPOL grid (Fig. 1). Moreover, it occurs mostly on abandoned fields (Fig. 2) and its known localities are concentrated in the north-eastern and southern parts of the country (Fig. 1). *Solidago × niederedederi* is a new taxon in the flora of the Toruń Basin and Bielsk Plain.

Explanations: The list concerns new and known records of the hybrid in Poland and is arranged by the ATPOL cartogram codes (capital letters indicate 100-km squares, numbers indicate 10-km squares). The cartogram units (10-km squares) in which the hybrid has been recorded for the first time are indicated with bold. The list includes the name of the locality, type of habitat, date of collection, name of collector, and an acronym of the herbarium in which the voucher specimens are deposited. Localities situated within the same cartogram unit are separated by a semicolon.

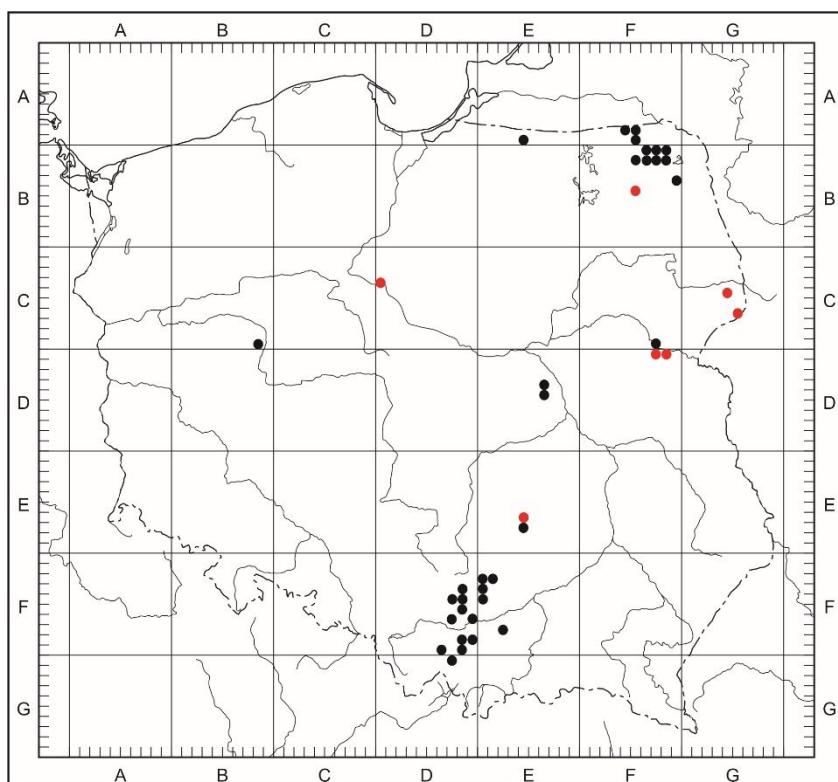

Fig 1: An updated distribution map of *Solidago × niederedederi* in Poland using the ATPOL cartogram grid (red dots indicate cartogram units in which the hybrid has been recorded for the first time, black dots indicate cartogram units in which the hybrid has been previously recorded).

Discussion

Distribution of natural hybrids between alien and native vascular plant species is poorly recognized in Poland (Pliszko 2015b). Unfortunately, the hybrids are easily overlooked during field surveys due to close resemblance to their parental species (Preston & Pearman 2015). Nevertheless, biological recording of hybrids between alien and native species is useful for classification of alien species (Blackburn *et al.* 2014). *Solidago ×niederederi* is one of the best-documented hybrids between alien and native plant species occurring in Poland (Pliszko 2015b, Pliszko & Zalewska-Gałosz 2016, Pliszko & Kostrakiewicz-Gierałt 2017). It should be pointed out that the occurrence of *S. ×niederederi* reflects the ongoing invasion of *S. canadensis*. It is clearly noticeable in the north-eastern part of the country, especially on the outskirts of small towns such as Suwałki and Gołdap, where *S. canadensis* exponentially colonized numerous abandoned fields and ruderal ground during the last 10 years.

The first stand of *S. ×niederederi* in Toruń, north-central Poland, was discovered in 2012 (Rutkowski 2017). Initially, the hybrid was identified as *S. ×snarskisii* Gudžinskas & Žalneravičius, a hybrid between *S. gigantea* Aiton and *S. virgaurea* (Gudžinskas & Žalneravičius 2016), due to the co-occurrence of *S. gigantea* and *S. virgaurea* and absence of *S. canadensis* at the site occupied. Nevertheless, a critical revision on herbarium specimens of the hybrid from the above-mentioned locality revealed the identity of *S. ×niederederi*. It is commonly known that plant hybrids usually occur together with their parental species (Preston & Pearman 2015,

Stace *et al.* 2015). However, there are a few localities in Poland where *S. ×niederederi* was found without or only with one of its parental species. On the other hand, the presence of *S. ×snarskisii* in Poland is still likely since *S. gigantea* co-occurs with *S. virgaurea* in many regions of the country (Zajac & Zajac 2001).

Considering the predicted distribution of *S. ×niederederi* in Poland (Pliszko & Zajac 2016, Jaźwa *et al.* 2018) and newly presented records we surmised that the hybrid is commonly distributed throughout the country wherever its parental species occur in close proximity to each other. Similar assumptions were made on hybrid distribution in Austria (Pagitz 2016) and Lithuania (Gudžinskas & Žalneravičius 2016, Karpavičienė & Radušienė 2016). However, further studies on hybrid occurrence in Poland are needed. In this respect, we recommend investigating abandoned fields and other habitats abundantly occupied by *S. canadensis* and *S. virgaurea*. It is also worth mentioning that as an established alien spreading by wind-dispersed achenes (Pliszko & Kostrakiewicz-Gierałt 2017), *S. ×niederederi* may become an invasive species in the future. According to Pagitz (2016), due to its self-incompatibility, the hybrid can pose a threat to native *S. virgaurea* by introgressive hybridization. Moreover, it seems to be a strong competitor for insect pollinators (Pagitz 2016). In conclusion, we hope that botanists and ecologists will pay a lot more attention to the occurrence and negative impacts of *S. ×niederederi*.

Acknowledgements: The first author would like to thank Maja Graniszewska, Ph. D., curator of the Herbarium of the Faculty of Biology of the University of Warsaw, for the loan of herbarium sheet of *Solidago ×niederederi* collected by Ambrożewska. The study was financially supported by the Institute of Botany of the Jagiellonian University in Kraków (K/ZDS/006305).
