

SIMULTANEOUS INFLUENCE OF THE TRACK AXIS CURVATURE AND THE SUPPORT LINE OBLIQUITY AT RAILWAY BRIDGE SUPERSTRUCTURES WITH STEEL BEAMS EMBEDDED IN CONCRETE

Stănescu Răzvan Marian, Assistant Lecturer, PhD, Faculty of Railways, Roads and Bridges, Technical University of Civil Engineering Bucharest, Romania;

Stan Oana Mihaela, Lecturer, PhD, Faculty of Railways, Roads and Bridges, Technical University of Civil Engineering Bucharest, Romania.

Rezumat

Pentru domeniul deschiderilor mici ($L \leq 35.00\text{m}$) la podurile feroviare noi se recomandă și se utilizează suprastructurile cu grinzi metalice înglobate în beton, cu care se pot asigura exigențele de rezistență și mai ales de rigiditate, indiferent de viteza de circulație.

În toate prescripțiile de proiectare existente până în prezent pentru structurile de poduri cu grinzi metalice înglobate în beton, și, chiar în literatura tehnică de specialitate, există puține informații și date referitoare la influența oblicității rezemării și a curburii axei căii în concepția și calculul acestor tipuri de structuri.

În prescripțiile de proiectare calculul este unul simplificat, realizat pe o singură grindă longitudinală izolată din tablier, dacă se îndeplinesc anumite condiții legate de geometria structurii (oblicitate, curbura). Dacă aceste condiții nu sunt îndeplinite se recomandă analiza cu programe de element finit.

Articolul își propune să studieze situațiile în care nu sunt îndeplinite condițiile prescripțiilor de proiectare.

Cuvinte cheie: oțel, beton, curbura, oblicitate.

Abstract

For new railway bridges with small spans ($L \leq 35.00\text{ m}$) superstructures with steel beams embedded in concrete are recommended and used, which can ensure the requirements of strength and especially stiffness, regardless of velocity.

In all the design prescriptions used so far for superstructures with steel beams embedded in concrete, and even in the technical literature, there is little information and data on the influence of the support line obliquity and the track axis curvature in the design and calculation of these types of structures.

In the design code, if certain conditions related to the geometry of the superstructure are met (obliquity, curvature) the calculation is a simplified one, made on a single isolated longitudinal beam of the deck; otherwise, if the conditions are not met, finite element program analysis is recommended.

The article aims to study the situations in which the requirements of the design prescriptions are not met.

Keywords: steel, concrete, curvature, obliquity.

1. PRESENTATION OF BRIDGE STRUCTURES ANALYZED [4]

Three simple supported bridges with steel beams embedded in concrete, with $L=10\text{m}$, $L=20\text{m}$ and $L=30\text{m}$ spans, were chosen for the study. For these, the support line obliquity (40^G , 50^G and 60^G) and the track axis curvature (100m ... 1500m) were varied.

The *Design Tables for Filler Beam Railway Bridges* [4], published by the International Union of Railways, has been the guideline for the constructive solutions of the three analyzed bridges. For the bridge with $L=10\text{m}$ span and a B track category, at a maximum speed of 160Km/h, the constructive solution consists of six steel beams HEA400 in cross-section, as shown in Figure 1. For the bridge with $L=20\text{m}$ span the constructive solution consists of six HEB800 steel beams (see Figure 2) and for the bridge with $L=30\text{m}$ span the constructive solution consists of six HLB1100 steel beams (see Figure 3).

In all three cases a deck width of 4m was obtained.

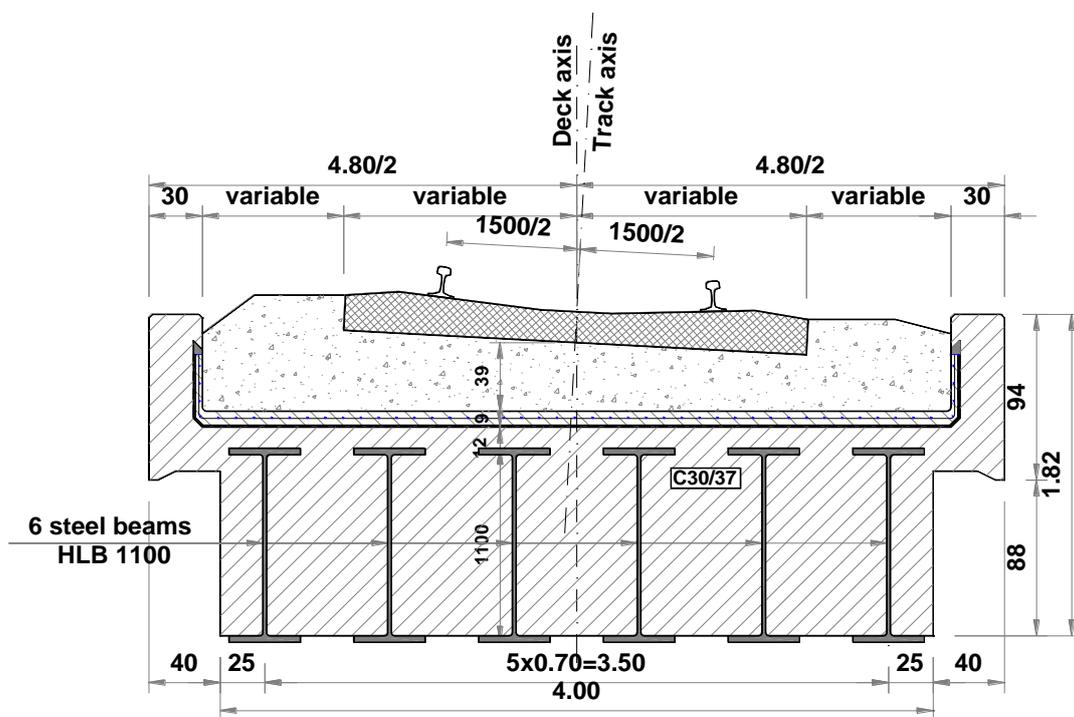

Figure 3. Constructive solutions for bridge with L=30m span

2. PRESENTATION OF THE CALCULATION MODELS [4]

Structures were analyzed with the Lusas FEA software, using 3D type “Stress” finite elements to model them.

To be able to observe the influence of support line obliquity and track axis curvature, bridges were first analyzed without support line obliquity and in alignment.

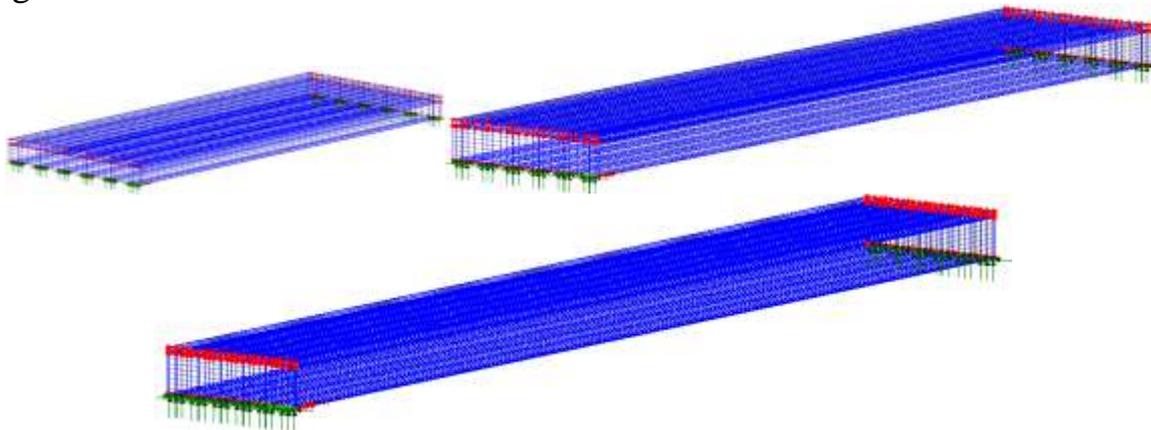

Figure 4. 3D view of the calculation models for bridges with 10m, 20m and 30m spans without support line obliquity

- **Bridge with L=10m span**

The calculation model contains 23200 “3D” finite elements type "Stress" HX8M and 28674 nodes, resulting 86022 degrees of freedom, as shown in Figure 5.

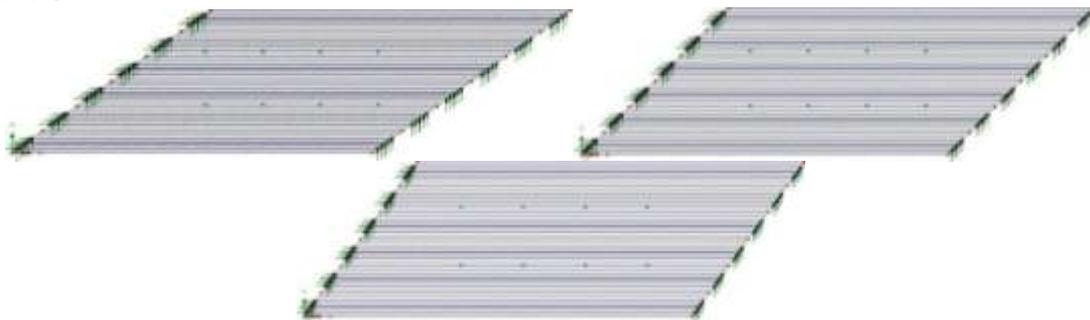

Figure 5. Plane view of the calculation models for bridge with 10m span and 40° , 50° and 60° support line obliquity

Figure 6. The cross-section of the bridge with L=10m span

- **Bridge with L=20m span**

The calculation model contains 47880 “3D” finite elements type "Stress" HX8M and 57387 nodes, resulting 172161 degrees of freedom (see Figure 7).

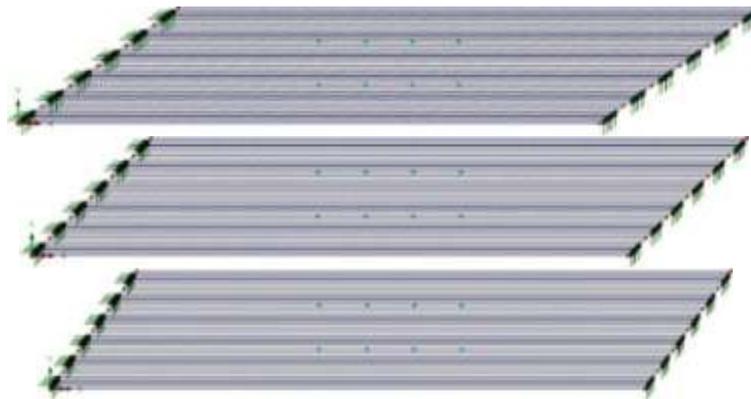

Figure 7. Plane view of the calculation models for bridge with 20m span and 40^{G} , 50^{G} and 60^{G} support line obliquity

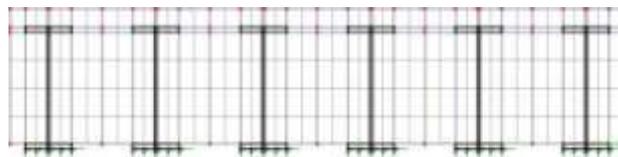

Figure 8. The cross-section of the bridge with L=20m span

- **Bridge with L=30m span**

The calculation model contains 51600 “3D” finite elements type "Stress" HX8M and 60903 nodes, resulting 182709 degrees of freedom (see Figure 9).

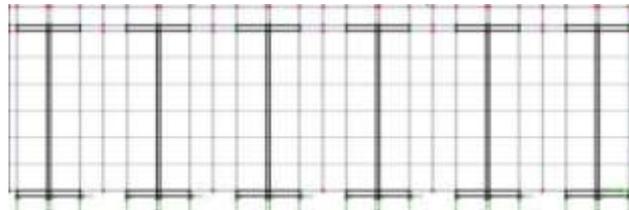

Figure 10. The cross-section of the bridge with $L=30\text{m}$ span

The calculation models were analyzed under the effect of permanent loads and the LM71 convoy.

3. SUMMARY PRESENTATION OF THE RESULTS OBTAINED USING THE LUSAS FEA SOFTWARE

From the analysis the following sizes proposed to be compared were extracted:

- Maximum deflection of the deck from permanent loads and LM71;
- Bending moments from permanent loads and LM71 in the midspan on each isolated longitudinal composed beam from the deck.

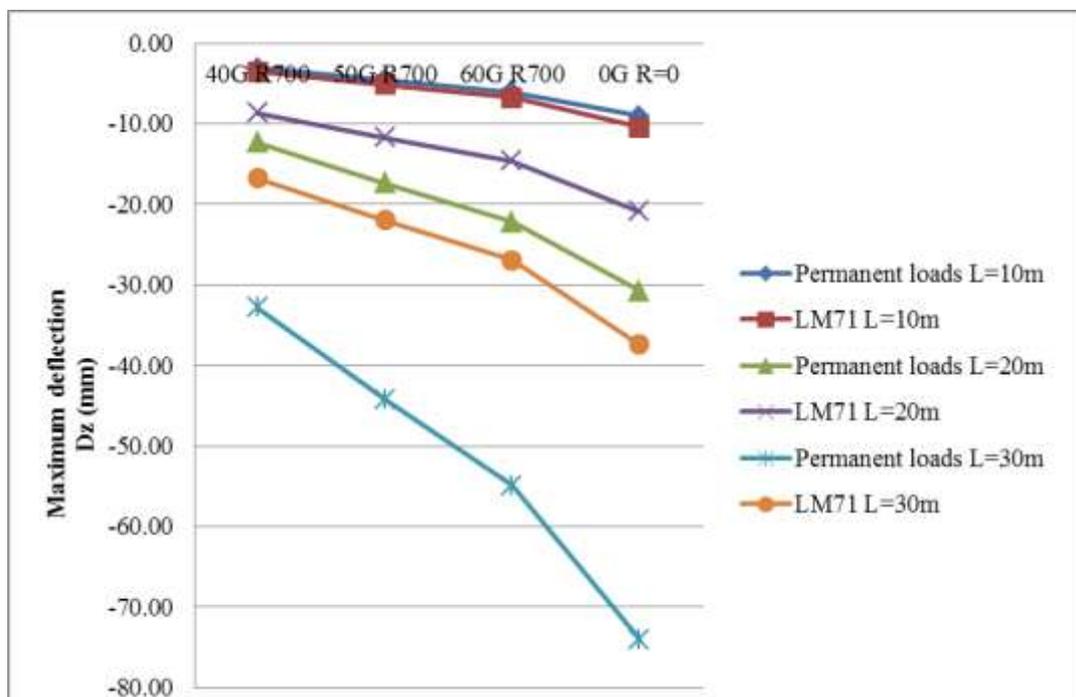

Figure 11. Maximum deflection variation depending on deck support line obliquity and bridge span for $R=700\text{m}$

4. CONCLUSIONS

Regarding the maximum deflections of the deck (ΔZ_{max}), their values are much lower as compared to those from the situation of bridges without support line obliquity (see Figure 11).

Their values, depending on the support line obliquity, are between 32,8% and 73,5% of those obtained for bridges without support line obliquity. This is normal as with the increase of the support line obliquity the deck becomes more rigid in the longitudinal direction. From the analysis of Table 1, it is observed that the maximum deflection increases with increasing the opening and the support line obliquity.

Regardless of opening and support line obliquity, maximum deflection values occur for a radius of $R=700m$, for which the values of centrifugal force are maximum.

It can be noted that, regardless of support line obliquity, the maximum bending moment at small openings occurs for the radius $R=700m$, for which the centrifugal force is maximum. With the increase of the opening, the maximum value of the bending moment occurs for the radius $R=100m$, because, geometrically, the external forces are moving away from the axis of the deck.

The fact that the track axis is curved on the bridges with support line obliquity does not significantly change the values of the bending moments. An increase in the maximum bending moment of about 5% is recorded in the case of the bridge with 10m opening, 3% in the case of the bridge with 20m opening and 2% in the case of the bridge with 30m opening, as seen/shown in Figure 18.

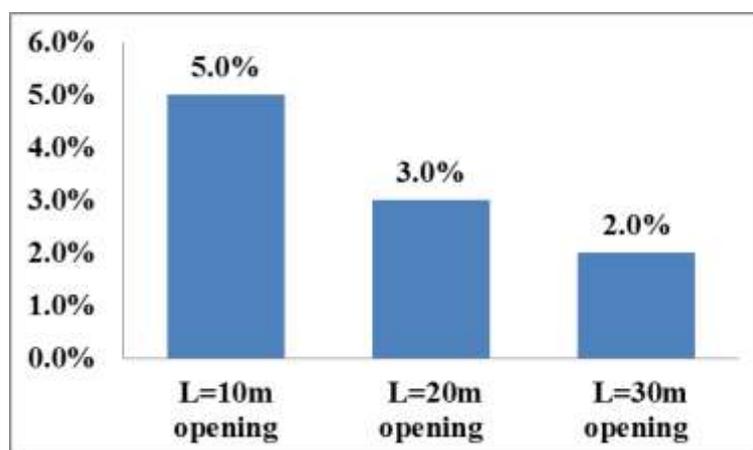

Figure 18. The increase of maximum bending moment due to track axis curvature presence on bridges with support line obliquity

The overall conclusion is that the support line obliquity dictates the behavior of the analyzed structures, the presence of the curve does not significantly influence the results that were compared. In the case of bridges with support line obliquity there is a great deal of stress in the support zones on the short diagonal of the deck. So, great care must be taken in the design of the supports and of the end zones on the short diagonal of the deck.
