# ON ONE TYPE OF COMPACTIFICATION OF POSITIVE INTEGERS 

Milan Paštéka

#### Abstract

The object of observation is a compact metric ring containing positive integers as dense subset. It is proved that this ring is isomorphic with a ring of reminder classes of polyadic integers.

Let $\mathbb{N}$ be the set of positive integers. A mapping $\|\cdot\|: \mathbb{N} \rightarrow<0, \infty)$ will be called norm if and only if the following conditions are satisfied for $a, b \in \mathbb{N}$

$$
\|a\|=0 \Leftrightarrow a=0, \quad\|a+b\| \leq\|a\|+\|b\|, \quad\|a b\| \leq\|b\| .
$$

There are various examples of norms on $\mathbb{N}$. One of these is polyadic norm defined in $[\mathrm{N}]$, [N1]. We start by a generalization of polyadic norm. Denote by $a+(m)$ the arithmetic progression with difference $m$ which contains $a$. Instead of $0+(m)$ we write only ( $m$ ).

A subset $A \subset \mathbb{N}$ we call closed to divisibility or shortly CD-set if and only if

$$
1 \in A, \quad m \in A, d \mid m \Rightarrow d \in A, \quad m_{1}, m_{2} \in A \Rightarrow\left[m_{1}, m_{2}\right] \in A
$$

for $d, m, m_{1}, m_{2} \in \mathbb{N}$.
Suppose that $A$ is infinite CD-set and $\left\{B_{n}\right\}$ is such sequence elements of $A$ that for every $d \in A$ there exists $n_{0}$ that $d \mid B_{n}$ for $n>n_{0}$. It is easy to see that the mapping

$$
\|a\|_{A}=\sum_{n=1}^{\infty} \frac{h_{n}(a)}{2^{n}}
$$

for $a \in \mathbb{N}$, where $h_{n}(a)=1-\mathcal{X}_{\left(B_{n}\right)}$, is a norm. This norm will be called generalized polyadic norm and the completion with respect the metric given by this norm will be called the ring of generalized polyadic integers.

[^0]
## MILAN PAŠTÉKA

If $A=\mathbb{N}$ and $B_{n}=n$ !, we get polyadic norm and the completion will be the ring of polyadic integers. In the case $A=\left\{p^{n} ; n=0, ., 2, ..\right\}$ and $B_{n}=p^{n}$ for a given prime $p$ we a obtain $p$-adic norm and the completion will be the ring of $p$-adic integers.

In the following text we shall assume that there is given a compact metric space $(\Omega, \rho)$ containing $\mathbb{N}$ as a dense subset. We suppose that the operations addition and multiplication on $\mathbb{N}$ are continuous and are extended to whole $\Omega$ to continuous operations. Thus $(\Omega,+, \cdot)$ is a topological commutative semiring.

Since $\Omega$ is compact, we can suppose that there exists an increasing sequence of positive integers $\left\{x_{n}\right\}$ convergent to an element of $\Omega$. Put

$$
a_{n}=x_{2 n}-x_{n}, \quad n=1,2, \ldots
$$

Then

$$
\begin{equation*}
a_{n} \geq n \quad \text { and } \quad a_{n} \rightarrow 0 \tag{1}
\end{equation*}
$$

in the topology of $\Omega$.
For $\beta \in \Omega$ and $b_{n} \rightarrow \beta, b_{n} \in \mathbb{N}$ we can consider the sequence of positive integer $\left\{a_{k_{n}}-b_{n}\right\}$, for a suitable increasing sequence $\left\{k_{n}\right\}$, such that

$$
a_{k_{n}}-b_{n} \rightarrow \beta^{\prime}, \quad \text { where } \quad \beta+\beta^{\prime}=0
$$

We see that $(\Omega,+)$ is a compact group.
Clearly, for every $m \in \mathbb{N}$ there holds $c l(r+(m))=r+m \Omega$, where $m \Omega$ is the principal ideal in the ring $(\Omega,+, \cdot)$ generated by $m$. This yields

$$
\begin{equation*}
\Omega=m \Omega \cup(1+m \Omega) \cup \cdots \cup(m-1+m \Omega) . \tag{2}
\end{equation*}
$$

Since the divisibility by $m$ in $\mathbb{N}$ is not necessary equivalent with the divisibility by $m$ in $\Omega$, it is not assumed that the last decomposition is disjoint.

Lemma 1. Let $m \in \mathbb{N}$ be such positive integer that it is also the minimal generator of the ideal $m \Omega$. Then every positive integer is divisible by $m$ in $\mathbb{N}$ if and only if it is divisible by $m$ in $\Omega$.

Proof. One implication is trivial. Suppose now that some positive integer $a$ is divisible by $m$ in $\Omega$. Thus $a \in m \Omega$. Put $d=(a, m)$-the greatest common divisor in $\mathbb{N}$. Then $d=a x+m y$ for certain integers $x, y$. This yields $d \in m \Omega$. We get $d \Omega=m \Omega$ and the minimality of $m$ implies $m=d$.

For every $n \in \mathbb{N}$ we can define $g(n)$ as the minimal positive generator of $n \Omega$. Put $\mathcal{A}=\{g(n) ; n \in \mathbb{N}\}$.

The set $r+m \Omega$ is closed and so from (2) we see that also open, which we refer as clopen set.

It is easy to check that the set $\mathcal{A}$ is a CD-set.

## ON ONE TYPE OF COMPACTIFICATION OF POSITIVE INTEGERS

Let $\left\{a_{n}\right\}$ be the sequence of positive integers given in (1). Clearly,
this yields

$$
\bigcap_{n=1}^{\infty} a_{n} \Omega=\{0\}
$$

$$
\begin{equation*}
\bigcap_{m \in \mathcal{A}} m \Omega=\{0\} \tag{3}
\end{equation*}
$$

So we obtain that the set $\mathcal{A}$ is infinite. Since $m \Omega$ is open for $m \in \mathcal{A}$, equality (3) implies that for each sequence $\left\{\alpha_{n}\right\}$ there holds

$$
\alpha_{n} \rightarrow 0 \Longleftrightarrow \forall m \in \mathcal{A} \exists n_{0} ; \quad n \geq n_{0} \Longrightarrow m \mid \alpha_{n}
$$

If we define the congruence by the natural manner: $\alpha \equiv \beta(\bmod \gamma)$ if and only if $\gamma$ divides $\alpha-\beta$, for $\alpha, \beta, \gamma \in \Omega$, then there holds:

$$
\alpha_{n} \rightarrow \beta \Longleftrightarrow \forall m \in \mathcal{A} \exists n_{0} ; \quad n \geq n_{0} \Longrightarrow \alpha_{n} \equiv \beta \quad(\bmod m)
$$

Thus the convergence can be metrised by the generalized polyadic norm. Let

$$
\mathcal{A}=\left\{m_{n}, n=1,2, \ldots\right\} \quad \text { and } \quad M_{n}=\left[m_{1}, \ldots, m_{n}\right], \quad n=1,2, \ldots
$$

then

We get the following

$$
\|\alpha\|_{\mathcal{A}}=\sum_{n=1}^{\infty} \frac{1-\mathcal{X}_{M_{n} \Omega}(\alpha)}{2^{-n}}
$$

Theorem 1. The metric $\rho$ is equivalent with the metric $\rho_{\mathcal{A}}$, where

$$
\rho_{\mathcal{A}}(\alpha, \beta)=\|\alpha-\beta\|_{\mathcal{A}} \quad \text { for } \alpha, \beta \in \Omega .
$$

So for every set $S \subset \Omega$ we have

$$
\begin{equation*}
c l(S)=\bigcap_{n=1}^{\infty}\left(S+M_{n} \Omega\right) \tag{4}
\end{equation*}
$$

Denote the Haar probability measure defined on $(\Omega,+)$ by $P$. For $m \in \mathcal{A}$ the decomposition (2) is disjoint and so $P(r+m \Omega)=\frac{1}{m}$. If we define the submeasure $\nu^{*}$ on the system of subsets of $\mathbb{N}$ as $\nu^{*}(S)=P(c l(S))$, we get from (4) and upper semicontinuity of measure that for each $S$

$$
\nu^{*}(S)=\lim _{n \rightarrow \infty} \frac{R\left(S: M_{n}\right)}{M_{n}}
$$

where $R\left(S: M_{n}\right)$ the number of elements of $S$ incongruent modulo $M_{n}$. Thus $\nu^{*}$ is the covering density defined in P .

Theorem 2. Let $\alpha, \beta \in \Omega$. There exist $\alpha_{1}, \beta_{1} \in \Omega$ such that the element $\delta=\alpha_{1} \alpha+\beta_{1} \beta$ divides $\alpha$ and $\beta$.

## MILAN PAŠTÉKA

Proof. Let $\left\{a_{n}\right\},\left\{b_{n}\right\}$ be the sequences of positive integers that $a_{n} \rightarrow$ $\rightarrow \alpha, b_{n} \rightarrow \beta$. Let $d_{n}$ the greatest common divisor of $a_{n}, b_{n}, n=1,2, \ldots$ Then $d_{n}=v_{n} a_{n}+u_{n} b_{n}$ for some $u_{n}, v_{n}$-integers. The compactness of $\Omega$ provides that $u_{k_{n}} \rightarrow \alpha_{1}$ and $v_{k_{n}} \rightarrow \beta_{1}$ for a suitable increasing sequence $\left\{k_{n}\right\}$. Put $\delta=\alpha_{1} \alpha+\beta_{1} \beta$. We see that $d_{k_{n}} \rightarrow \delta$. For $n=1,2, \ldots$ we have $a_{k_{n}}=c_{n} d_{k_{n}}$. Since $\left\{c_{n}\right\}$ contains a convergent subsequence, we get that $\delta$ divides $\alpha$. Analogously, it can be derived that $\delta$ divides $\beta$.

The element $\delta$ from Theorem 2 will be called the greatest common divisor of $\alpha, \beta$ and we shall write $\delta \sim(\alpha, \beta)$.
Corollary 1. If $p \in \mathcal{A}$ is a prime then for every $\alpha \in \Omega$ there holds $p$ divides $\alpha$ or $(\alpha, p) \sim 1$.

Proof. If $p$ does not divide $\alpha$ then $\alpha \in \Omega \backslash p \Omega$. Consider a sequence of positive integers $\left\{a_{n}\right\}$ which converges to $\alpha$. The set $\Omega \backslash p \Omega$ is open, thus we can suppose that $\left(a_{n}, p\right)=1$. This yields $\ell_{n} a_{n}+s_{n} p=1$ for suitable integers $\ell_{n}, s_{n}$. Since $\Omega$ is a compact space there exists an increasing sequence $\left\{k_{n}\right\}$ that $\ell_{k_{n}} \rightarrow \lambda, s_{k_{n}} \rightarrow \sigma$. And so $\lambda \alpha+\sigma p=1$.

Corollary 2 can be proved analogously
Corollary 2. An element $\alpha \in \Omega$ is invertible if and only if $(\alpha, p) \sim 1$ for every prime $p \in \mathcal{A}$.

Lemma 2. Each closed ideal in $\Omega$ is principal ideal.
Proof. Let $I \subset \Omega$ be closed ideal. Let $\alpha \in I$. Denote by $I_{\alpha}$ the set of all divisors of $\alpha$ belonging to $I$. The compactness of $\Omega$ yields that $I_{\alpha}$ is a closed set. From Lemma 2 we get that for every $\alpha, \beta \in I$ there exists $\delta \in I$ so that $I_{\delta} \subset I_{\alpha} \cap I_{\beta}$. And so it can be proved by induction that $I_{\alpha}, \alpha \in I$ is a centered system of closed sets. Thus its intersection is non empty, and contains an element $\gamma$. Then $I=\gamma \Omega$.

In the sequel we denote $\Omega$ the ring of polyadic integers, thus completion of $\mathbb{N}$ with respect to norm $\|\cdot\|_{\mathbb{N}}$ and we suppose that an infinite CD-set $A$ is given. The completion of $\mathbb{N}$ with respect to the norm $\|\cdot\|_{A}$ we denote as $\Omega_{A}$.

Lemma 2 provides that $\cap_{a \in A} a \Omega=\alpha \Omega$ for suitable $\alpha \in \Omega$.
We will prove the folowing
Theorem 3. The ring $\Omega_{A}$ is isomorphic with the factor ring $\Omega / \alpha \Omega$.
Proof. If a sequence of positive integers is Cauchy's with respect to $\|\cdot\|_{\mathbb{N}}$, then it is Cauchy's with respect to $\|\cdot\|_{A}$ as well.

If $\left\{a_{n}\right\},\left\{b_{n}\right\}$ are sequences of positive integer, then

$$
\left|\left\|a_{n}-b_{n}\right\|_{\mathbb{N}} \rightarrow 0 \Longrightarrow\right|\left\|a_{n}-b_{n} \mid\right\|_{A} \rightarrow 0
$$

## ON ONE TYPE OF COMPACTIFICATION OF POSITIVE INTEGERS

Therefore we can define a mapping $F: \Omega \rightarrow \Omega_{A}$ in the following way. If $\beta \in \Omega, b_{n} \rightarrow \beta$ with respect to $\|\cdot\|_{\mathbb{N}}$, then $F(\beta)$ is the limit of $\left\{b_{n}\right\}$ with respect to $\|\cdot\|_{A}$. Clearly, $F$ is a surjective morphism with kernel $\cap_{a \in A} a \Omega$ and the assertion follows.

Theorem 4. The ring $\Omega_{A}$ is an integrity domain if and only if $A=\left\{p^{n} ; n=\right.$ $0,1,2 \ldots\}$, where $p$ is a prime number.

Proof. Suppose that $A=\left\{p^{n} ; n=0,1,2 \ldots\right\}$. It suffices to prove that $\cap_{a \in A} a \Omega$ is a prime ideal. Let $\alpha, \beta$ do not belong to $\cap_{a \in A} a \Omega$. Then $\alpha=p^{k} \alpha_{1}, \beta=p^{j} \beta_{1}$, where $\left(p, \alpha_{1}\right) \sim 1,\left(p, \beta_{1}\right) \sim 1, j, k<\infty$. Thus

$$
\alpha \beta=p^{k+j} \alpha_{1} \beta_{1} \notin \cap_{a \in A} a \Omega .
$$

Assume that $A$ contains at least two different primes. The elements of the sequence $\left\{M_{k}\right\}$ can be decomposed into $M_{k}=d_{k} c_{k}$ such that

$$
\left(d_{k}, c_{k}\right)=1, \quad d_{k}>1, \quad c_{k}>1, \quad k=1,2, \ldots
$$

Let $\left\{k_{n}\right\}$ be a subsequence such that $d_{n_{k}} \rightarrow \delta, c_{n_{k}} \rightarrow \gamma$. Then $\gamma, \delta \notin \cap_{a \in A} a \Omega$ and $\gamma \delta \in \cap_{a \in A} a \Omega$, thus $\cap_{a \in A} a \Omega$ is not a prime ideal.
