ABSTRACT
Purpose. Biomechanical research conducted on hurdling are the basis for analysis of technique used in running disciplines. However, the 400 m hurdle run is an athletic discipline rarely subjected to individual biomechanical study. The aim of this study was to introduce the various forms of biomechanical studies on this difficult-to-quantify athletic event. Methods. In this study, 64 biomechanical articles were assessed, each covering various topics such as kinematics, dynamics, accelometrics and rhythm knowledge in the both the men’s and women’s 400 m hurdles. This was conducted with regard to the specificity of studies on the 400 m hurdles, including their types, methods and difficulties. The characteristics of the study were divided, among others, into: physiological effort, centrifugal force, dynamics of movement, stride rhythm, the level of abilities, laterality and type of body build. Results. Numerous sources allowed the creation of a general outline of present biomechanical studies. Conclusions. Within the context of the conducted analysis on the present state of biomechanical analysis on the 400 m hurdles, a number of basic principles were outlined that could determine the effectiveness of future research possibilities for scientists on the 400 m hurdles.

Key words: 400 m hurdles, biomechanics, kinematic, rhythm

Introduction

Track and field athletics is a discipline of sport that includes nearly 30 different forms of competition that test various fitness (motor) abilities and specific sporting techniques. The group of competitive sports that predominantly require fitness (motor) abilities include all forms of sprint and endurance competition (from the 800 m race to the marathon). The types of track and field events that have a significant (and sometimes dominant) component of testing motor skills and coordination (in sport, both of these components are classified as technique) are largely those that involve jumping and throwing.

Hurdling is a form of track and field competition that mixes both motor abilities (with emphasis on speed, dynamic strength and anaerobic endurance) and specific motor skills [1–3]. The first attempts at assessing the technical skills of sprint hurdle races occurred already at the beginning of the 20th century, when Frederick Webster compared the techniques of two hurdlers, the American Alfred Copland and English A.C.M. Croom [4].

The beginnings of such research on running technique were mainly based on observation and images, which included artistic paintings, stroboscopic observation, and the application of photography, especially time-lapse photography, being the early prototype of timed-sequence sports photography [5].

However, analysis of the techniques used in the hurdle run, on the basis of the above mentioned methods, only took on a larger role much later [6]. Those early attempts of analysis focused primarily on the more basic forms of physical activity in track and field, such as running, jumping and throwing [7]. A return to the imaging methods which evaluate the movement present in hurdling took place only after World War II and continues to this day [8].

The initial forms of assessing the techniques present in hurdle races were focused on sprint distances, such as the men’s 110 m hurdles or the women’s 80 (100) m hurdles [9–14]. However, the 400 m hurdles was, and still is, overlooked in the biomechanical analysis of track and field sports. Although both hurdle distance are frequently treated as one group of competition, there are fundamental differences between them, as found in biomechanical studies, where the most important of which are provided in Table 1.

The 400 m hurdles is one of the most interesting yet difficult track and field competitions. The characteristics of this form of competition can be made by using such phrases as “relative” or “indirectly related to”. Here are some examples:
1. The 400 m hurdles is still a “relatively” new form of competition, the first records in the 110 m hurdle were first noted only in the mid-19th century; for the 400 m hurdles, only 50 years...
Research conducted in field conditions, as a control is quite difficult and not very popular [25]. Research on the kinematic structure of race conditions competing at a lower level [24]. However, conducting some cases this kind of analysis is conducted on athletes such as in the 2000 Olympic Games in Sydney [23]. In largely on the world’s most important competitions, hurdles. Race analysis of the 400 m hurdles focuses on mic stepping, which is performed between successive strides. The results of empirical analysis to sports training are based on biomechanical studies that are mostly conducted on the 110 m hurdles to the 400 m hurdles. The details are presented in Table 3.

The smallest group of studies conducted on the 400 m hurdles are those of laboratory analysis. They focus mainly on issues related to strength as a static condition [29]. The difficulties in organizing studies on the movement structure and dynamics in the 400 m hurdles are due to a variety of reasons (Tab. 4). The regulations of the race (on different tracks, the positions of the hurdles in different spots), the specificity of training for competition (races are only in the summer) and a number of methodological dilemmas significantly impede conducting such tests.

The organization of biomechanical research on the 400 m hurdles requires a broader look at the specificity of both motor and technical skills in competition. It is difficult to directly transpose the results of studies conducted on the 110 m hurdles to the 400 m hurdles. The determinants of such biomechanical studies are presented in Table 5.

Attempts at conducting biomechanical analysis of running in the 400 m hurdles were concerned about previous research and studies connected with the improvement of the methodology and practical application of the results of empirical analysis to sports training. This problem can be presented as several points, some of which are emphasized below.

1. Methodological problems connected with biomechanical studies on the 400 m hurdles

An assessment of running techniques used in hurdles is based on biomechanical studies that are mostly focused on sprint distances, the men’s and women’s 100/110 m hurdles [6]. Started in the 1950s, attempts at objectively assessing the techniques of sprint hurdle races in the 1990s led to a discussion on the validity and reliability of the selection of the parameters that were used to assess the appropriate style of running [30–33]. Studies conducted on the 400 m hurdles pri-

HUMAN MOVEMENT
J. Iskra, M. Coh, Studies on the 400 m hurdles

primarily used accelometric analysis (see below); only in a few cases were efforts made at determining the methodological basis of biomechanical studies [21, 28]. These attempts, however, failed to arrive at clearly formulated conclusions as to the selection of the best options for testing in accurate, reliable and standardized conditions.

2. The selection of kinematic parameters in the evaluation of running techniques used in the 400 m hurdles

The most frequently used parameters in the evaluation of running techniques in hurdles were from movement kinematics. Such studies appeared during the 1980s and 1990s [9, 10, 34–36] and were highly diversified (both methodologically and thematically). The search for relevant factors that could assess the structure of hurdles running were concerned with several to several dozen parameters. However, in a few studies conducted on the 400 m hurdles, some of the selected parameters did not seem to be representative in assessing the effectiveness of various running techniques. In studies conducted by Iskra and Bacik [37], four basic parameters (mainly different stride lengths) were included; in Bollschweiler [35], 14 length and angular parameters were selected. The current state of research on the kinematic parameters of hurdles running (especially in attacking hurdles) for the 400 m distance does not allow for the strong selection of accurate and reliable timing, spatial and time-space parameters.

3. Dynamometric tests and the specificity of the 400 m hurdles

Research on ground reaction forces by using tenometric and piezoelectric platforms provides an indispensable element in biomechanical studies in track and field athletics, including hurdling. The increasingly widespread use of the devices produced by the Swiss company Kistler allows one to obtain relevant information on running the 400 m hurdles. As a general characteristic of the competition, the 400 m hurdle race is composed of a sprint with the need of jumping over 10 obstacles. Each take-off and landing is an indispensable part of the 400 m hurdles [18]. In empirical studies conducted on hurdling, dynamometric analysis was conducted by Rölla [26] and was also considered by the Polish hurdlers Dworak et al. [38].

4. The energy specificity in the 400 m hurdles and changes in hurdling technique

Scientific analysis on the 400 m distance (also with hurdles) found that maximum effort performed in a time less than 1 min was dominated by transforma-

5. Accelometric research as the basis for biomechanical research in running the 400 m hurdles

Biomechanical analysis on running the 400 m hurdles has been from the beginning connected with the evaluation of hurdling techniques through the use of sequence photography and research performed on time differences in certain parts of the race. Accelometric analysis constitutes a major part of the publications published to date that merge the 400 m hurdles and the method of biomechanical research on human movement. Since the 1968 Olympic Games in Mexico, analysis in the changes of running speed in the 400 m hurdles have become an indispensable part of scientific investigation in this form of competition [24, 46]. These studies have become a sort of inspiration for studies conducted later in analyzing athletes of a lower level [24, 47]. Analysis in the changes of speed (and mainly its reduction after 150 m) are significant in the organization of sports training. Assessment of the differences between running “tactics” at different levels (juniors–seniors, women–men) is only the beginning for further research. Additional questions should be asked on the assessment of which parts of the run can be the most significant in winning the race. Not only are absolute results important (finishing times), but also the impact of deceleration during the race.

6. Running “rhythm” in the 400 m hurdles as the most used and most enigmatic term in competitive hurdling

The concept of rhythm, understood within the theory of motor coordination, is clearly formulated.
Rhythm in hurdling is a term that is found more in practical training and competition than in scientific literature. A review of the definition that is used to define “hurdling rhythm” in the 400 m hurdles was conducted by Iskra [47] and distinguished three variants:

1. Rhythm is the number of steps performed in each successive “rhythmic unit”,
2. Rhythm as the number of steps in relation to the time spent covering the specific parts of the race (frequency of steps).
3. Rhythm is the optimized (in terms of the number of steps and running pace) form of running the entire distance in the shortest possible time by taking into consideration the level of preparation of one’s motor skills, technique and somatic build.

This relatively expanded definition illustrates the complexity of “rhythm” in the 400 m hurdles. The number of steps taken in the nine successive distances between the hurdles implies using both the right and left legs to attack the hurdles, under different conditions of energy-related effort (rest-fatigue) and the course structure (straight or turn). Changes in the attacking legs of hurdlers with different rhythms are presented in Table 6 [22].

7. Attacking hurdles on the straight and turns – the problems of training and scientific analysis

Running the 400 m hurdles is an alternating combination of attacking hurdles on the straight and turns of the track. The running distance after the turn is considered one of the two most difficult parts of the race, the acceleration phase and the first phase of fatigue due to anaerobic work, closely tied with the changes of step rhythm (Tab. 6).

In the more than 100-year history of biomechanical research in sport, there is still no study which analyzes the problems of different techniques in hurdling on the straight and turns. The question of differences in the biomechanical parameters of running on the different parts of the course have only been conducted on a flat distance of 400 m [48]. If we were to add the level of fatigue (e.g., during the second turn) as a factor to the entire distance, the need for research on the techniques of attacking hurdles on turns appears to be even more necessary.

8. Lateralization (functional asymmetry) – not only scientific problems, but also of sport

The aspects of the human body’s functional asymmetry are present in many sports that require the effective use of, mainly, two limbs (e.g., the left and right legs in soccer, the left and right hand in basketball or boxing). An excellent example of track and field athletic competition that takes the problem of lateralization into account is the 400 m hurdles. It is known that the “dominant” lower limb in hurdling is the left leg, which minimizes the negative effects of centrifugal force.

The specificity of the 400 m hurdles excludes (except in certain cases) the possibility of attacking the hurdles with only one lead leg. This is connected to instances of 13- and 15-step rhythm. However, such a concept is not entirely optimal within the context of a runner changing stride length. Due to increasing fatigue in the second part of the 400 hurdles race not only is there a reduction in speed, but also the hurdlers’ stride length (from 3.73 cm to 3.39 cm). Therefore it appears that it is necessary for the hurdler to change his attacking leg, and by changing the attacking leg, we need to be aware of significant changes in the training process of hurdlers. Similar to how basketball and handball players, in certain circumstances, need to throw using either their right or left hand, the same applies for running in the 400 m hurdles, which involves using both legs for attacking hurdles.

Research conducted by Iskra and Waalszczyk [22] and Iskra [49] found that hurdlers in the 400 m hurdles exploit their strength in different ways (with their “dominant” leg) as well as using their weaker (“alternative”) leg in different ways when attacking hurdles. However, the problems of the functional differentiation of the “attacking leg” have been more closely examined by trainers than by sport researchers.

9. The strength and direction of wind and changes in running rhythm in the 400 m hurdles

Accelometric research and cinematic analysis on the 400 m hurdles does not take into account the ef-
fect of wind speed and direction on the choice of the attacking leg, running rhythm and, consequently, on attacking hurdles. An example of the importance that weather conditions (in this case wind speed and direction) have on tactics and technique used in the 400 m hurdles was during the elimination trails during the Olympic Games in Sydney, when the wind force on the last straight was more than -4 m/s. Previous analyses on the impact of wind speed and direction on one lap race results were only conducted on the straights of a track [50–52].

Analyses in the changes of technique between the straights, by taking into consideration the impact of wind, seems to be necessary from the standpoint of practical training. This is particularly important in competition, which can take place in a variety of directions and on tracks of varying curvature. Some of the most radical changes are proposed by Mureika [55], who demanded the recalculation of competition results in sprint races by including wind strength and the height above sea level of where the competitions took place. Questions on the impact of wind on the way (style, technique) hurdling is performed still remain open. Recent analysis conducted by Quinn [53] provides interesting data on hurdling on different tracks during the same (measured) wind speed.

10. Comparison of the specificity of the 400 m hurdles to other track and field competitions

The history of running the 400 m hurdles has become a derivative of sprint hurdles race (110 m hurdles) and the 400 m dash. Comparisons (including biomechanical) among these three types of competitions have become popular in the evaluation of techniques in running the 400 m hurdles in the 1970s [55]. The understanding of the 400 m hurdles as an extended form of the 110 m hurdles have for long hindered biomechanical studies comparing it to completely different distances. Moreover, all studies on hurdling frequently combine both distances as one. Recent studies on the 400 m hurdles suggest that it is (mainly due to the obstacles present) connected more to the 3000 m [25, 26] steeplechase run. Thirty years of physical education progress was not enough to clearly state that the 400 m hurdles is a specific form of competition, distinct from the 110 m hurdles, 400 m dash or the 3000 m steeplechase. The main differences are provided in Table 7.

11. The problem of motor control and the specificity of hurdles

The effort required in hurdling is connected to the repeatability of specific movement sequences in jumping over the hurdles and then running to the next obstacle. The so-called rhythmic unit [3, 57], in the case of running the 110 m hurdles, are associated with running in a 3-step rhythm, while running the 400 m hurdles requires a variable number of steps (12–19).

Analysis of the movement sequences is characteristic of research in the field of motor control, where it is usually associated with movements with a limited aspect of mobility (e.g., typing, playing the piano, etc.) [58, 59].

Comparison of the movement sequences in the range of the so-called fine motors have in fact much in common with the rhythmic units present in the 400 m hurdles. Such a hypothesis was used in hurdles research conducted by Hay and Schoebel [60]. Clearing obstacles of low height during walking and running is a significant part of empirical research that borders with motor and biomechanical theory. Referring the experience of hurdlers in clearing obstacles finds that this group of track and field competitors can provide a stimulus for wider, non-sport empirical analysis [61, 62].

The problems associated with the use of biomechanical methods in controlling the training as well as assessment of competition in the 400 m hurdles is connected to numerous problems taken from the wider understood aspect of physical culture. Comprehensive analysis that takes into account a wide range of purely biomechanical problems as well as the necessary information on the theory of sports training, stress parameters, anthropometric measurements, etc., belong to the biomechanical studies of the past. This applies not only hurdling, but all professional sports.

Within the evaluation of the specific problems connected with the biomechanics of running the 400 m hurdles, several important aspects need to be taken into account:

1. The differences in the method of teaching hurdling techniques (e.g., analytic, synthetic, and recreational) that have an effect on improving hurdling techniques, assessed on the basis of selected kinematic and dynamic parameters [63].
2. The effect of body build (e.g., height or leg length) on selecting the optimal running rhythm or hurdling technique [64].
3. Changing sports training (which includes measures used in the improvement of motor skills
4. Changes in the regulations of hurdling in terms of biomechanical analysis [66, 67]. There are many problems associated with biomechanical analysis performed on the 400 m hurdles. The past efforts of researchers could be considered being partial, and perhaps, even, rudimentary. Attempts at comprehensive research on hurdling have, so far, included only the 110/100 m hurdles [13, 56, 68]. There is a necessity in developing a comprehensive study on only the 400 m hurdles, with the proposal for such a study provided in Table 8.

Conclusion

Within the context of the conducted analysis on the present state of biomechanical analysis on the 400 m hurdles, a number of basic principles can be stated that could determine the effectiveness of future analyses.

- The recognition of the 400 m hurdles as a specific, autonomous form of track and field competition, which differs from sprint hurdles performed on the track straight
