TO THE EDITOR

Non-alcoholic fatty liver disease (NAFLD) is an emerging public health issue, being not only a major cause of liver-related morbidity and mortality worldwide, but also an independent risk factor for chronic diseases.^[1] NAFLD is now considered the hepatic border of metabolic syndrome, supported by a high-calorie dietetic regimen, in the presence of a genetic profile.^[2] Several molecules produced by adipose tissue such as adiponectin, leptin, visfatin and resistin, and pro-inflammatory cytokines such as tumor necrosis factor- α , and interleukins can be involved in the pathogenesis of NAFLD.^[1,2] In particular, resistin is a 10 kDa dimeric protein secreted by adipose tissue and macrophages, the human gene codes for a 94 amino acids polypeptide. Resistin circulates in two distinct forms, the HMM hexamer (high-molecular-mass) that is the predominant state, and LMM complex (low-molecular-mass) the more bioactive peptide. It was reported in the studies on animal models that liver is a major target of resistin; in fact, it is involved in glucose and lipid metabolism, contributing to the development of insulin resistance and obesity.^[2]

Resistin is also expressed in liver cells, where its production seems to increase with the progression of liver damage. In histologically confirmed NAFLD studies, the higher circulating levels of resistin were reported in patients with simple fat accumulation, or non-alcoholic steatohepatitis than in controls.^[3] However, literature also reported similar resistin levels in patients with simple steatosis compared to steatohepatitis.^[4]

On this topic, we have previously published a study on the relationship between the serum levels of a selected set of adipokines included resistin, and NAFLD in overweight patients compared to the lean controls.^[5] We found no differences in the resistin serum levels in the patients with NAFLD compared to controls. However, we also demonstrated a negative correlation between resistin concentration and echographic stage of hepatic fat accumulation. These observations are similar to previous reports and suggest that the role of resistin in the pathogenesis of NAFLD can be limited. However, resistin could circulate in different molecular isoforms in peripheral human blood, and this might be the cause of the mistakes for the determination of its serum levels and for the comparison of the levels measured with different assay systems.

It seems reasonable to conclude that, in line with these conflicting data, the role and the contribution of resistin in NAFLD development and progression should be clarified in further studies.
