FOREWORD

This issue of the journal acknowledges the wide scope of topics existing in the research field related to the environment and climate technologies, the research and development specifics and analysis of methodologies.

Authors of the journal represent various countries and continents. The topic scope reflected includes urban environment impact analysis on climate change, analysis of eco-efficiency elements in Southern Europe, research on the living environment behaviour in Northern Europe of reconstructed and reorganized river-beds and module development of agro-ecological zoning in South America.

The energy sector and its sustainable development is of great importance in this issue; matters related to changes in engineering, technical and operational parameters. Recently the attitude towards renewable energy resources has changed by renewables replacing fossil energy resources in district heating systems. This resource usage shift could not have been done without reorganization of distinct heating systems and implementation of energy accumulation which demonstrates analysis of the urban environment energy supply and possible solutions.

Articles in the journal focus on solutions to minimise anthropogenic impact on the environment and global warming effect.

I wish each reader to discover interesting ideas that could not only help to better understand the significant role of scientific development in the field of environment and climate technology but also increase scientific achievements and quality.
